- /srv/murmur

# Les mails

## Configuration des clients:

### SMTP

### IMAP

mail.ppsfleet.navy, ssl/tls, 993

## Le serveur

Le serveur est composé de

- ~Opensmtpd~ Exim - serveur smtp ( envoi/reception de mail )
- Dovecot - serveur imap ( pour stocker les mails, et lire ses mails avec un client )
- Sieve (dans dovecot): rules pour trier les mails dans des dossiers etc...
- Dkimfilter - signe les mails avec la clé public du serveur
- Des champs dns - `/var/named/ppsfleet.navy.d/ppsfleet.navy.mail.include`

Tout est géré via systemd, installé sur l'auth

### Dovecot

`/etc/dovecot/dovecot.conf`

*Les fichiers dans /etc/dovecot/conf.d ne sont pas lues...*

```

ssl = required
ssl_cert = </etc/letsencrypt/live/mail.ppsfleet.navy/fullchain.pem
ssl_key = </etc/letsencrypt/live/mail.ppsfleet.navy/privkey.pem

ssl_min_protocol = TLSv1.2
ssl_prefer_server_ciphers = yes
ssl = required
disable_plaintext_auth = yes

protocols = lmtp imap sieve

service lmtp {
    unix_listener lmtp {
        user = vmail
        group = vmail
    }
}

protocol lmtp {
    mail_plugins = $mail_plugins sieve
}

service managesieve-login {
    inet_listener sieve {
        port = 4190
    }

    #inet_listener sieve_deprecated {
    #    port = 2000
    #}
}

# Number of connections to handle before starting a new process. Typically
# the only useful values are 0 (unlimited) or 1. 1 is more secure, but 0
# is faster. <doc/wiki/LoginProcess.txt>
service_count = 1

# Number of processes to always keep waiting for more connections.
process_min_avail = 0

```

```
# If you set service_count=0, you probably need to grow this.
vsz_limit = 64M
}

service imap-login {
    inet_listener imap {
        port = 143
    }
    inet_listener imaps {
        port = 993
    }
}

service auth {
    # SASL
    unix_listener auth-client {
        mode = 0600
        user = mail
        group = mail
    }
}

passdb {
    driver = passwd-file
    args = scheme=SHA512-CRYPT /etc-mails/passwd.txt
}

userdb {
    args  = uid=vmail gid=vmail home=/data-mails/mailbox/%d/%n
    driver = static
}

#userdb {
#    driver = passwd-file
#    args = /etc/dovecot/users.txt
```

```

#     override_fields = uid=vmail gid=vmail home=/home/vmail/%n
#}

namespace inbox {
    # Namespace type: private, shared or public
    type = private

    # Hierarchy separator to use. You should use the same separator for all
    # namespaces or some clients get confused. '/' is usually a good one.
    # The default however depends on the underlying mail storage format.
    separator = '/'

    inbox = yes
}

mail_location = maildir:/data-mails/mailbox/%d/%n

```

## Exim

La conf exim est divisé en plusieurs section. [https://www.exim.org/exim-html-current/doc/html/spec\\_html/ch-the\\_default\\_configuration\\_file.html](https://www.exim.org/exim-html-current/doc/html/spec_html/ch-the_default_configuration_file.html)

Les paramètre globaux (en haut), tel que les certificats et d'autres truc généraux

la section **begin acl.** Vérifie si on accepte d'envoyer le mail selon l'émetteur, à qui on l'envoie, le type mime etc...

On a configuré les sections via ces lignes:

```

acl_smtp_mail =      acl_check_mail
acl_smtp_rcpt =      acl_check_rcpt
ifdef _HAVE_PRDR
acl_smtp_data_prdr =  acl_check_prdr
.endif
acl_smtp_data =       acl_check_data
acl_smtp_mime =       acl_check_mime

```

la section **begin routers.**

The routers that you find under 'routers configuration' contain conditions that determine under which conditions 'something' happens to the mail. What happens next is determined by the transports under 'transport configuration'.

```
system_aliases:  
  driver = redirect  
  allow_fail  
  allow_defer  
  data = ${lookup{$local_part@$domain}!search{/etc-mails/aliases.txt}}  
# user = exim  
  file_transport = address_file  
  pipe_transport = address_pipe
```

```
localuser:  
  debug_print = "R: local_user for $local_part@$domain"  
  driver = accept  
  domains = +local_domains  
# local_part_suffix = +* : -*  
# local_part_suffix_optional  
  transport = dovecot_lmtp  
  cannot_route_message = Unknown user
```

## la section **begin transports**

la section **begin retry**. Règle de retry

la section **begin rewrite**. vide

la section **begin authenticators**. Pour l'authentification.

On utilise dovecot.

```
begin authenticators  
  
dovecot_plain:  
  driver = dovecot  
  public_name = PLAIN  
  server_socket = /var/run/dovecot/auth-client  
  server_set_id      = $auth1
```

Pour que ça fonctionne on doit avoir exim lancé avec le groupe mail. C'est dans le fichier  
`/etc/sysconfig/exim`

## Sieve

Pour avoir sieve, il faut installer le paquet `dovecot-pigeonhole`. Puis tout se joue dans dovecot. La conf du dessus est configuré pour sieve.

[https://doc.dovecot.org/2.3/configuration\\_manual/sieve/configuration/](https://doc.dovecot.org/2.3/configuration_manual/sieve/configuration/)

Il faut aussi configurer l'interface web dans `/etc/roundcubemail/managesieve.inc.php.dist`

> \$config['managesieve\_host'] = 'localhost:4190'; (pour correspondre à la conf de dovecot)

## Les utilisateurs:

Il y a 3 fichiers:

- Les noms de domaines: `/etc-mails/domains.txt`
- Les mot de passe: `/etc-mails/passwd.txt`
- Les alias (réception): `/etc-mails/aliases.txt`

Pour générer le hash du mot de passe: `doveadm pw -s SHA512-CRYPT`

**todo:** unifier tout ça, avec auth.ppsfleet.navy si possible

# Onlyoffice

## Base

Onlyoffice est installé en suivant la doc suivante <https://helpcenter.onlyoffice.com/installation/docs-community-install-centos.aspx>

Le service est `supervisord`.

## Configuration

La config nginx est dans `includes/ds-*.conf`, `conf.d/http-common.conf` et `site-available/office.cloud.ppsfleet.navy.conf`

La config de l'éditeur se trouve dans `/etc/onlyoffice/documentserver/local.json`, c'est dans ce fichier qu'est défini le jeton secret.

Ne pas oublier de mettre :

```
host    onlyoffice    onlyoffice    ::1/128        trust
host    onlyoffice    onlyoffice    127.0.0.1/32    trust
```

dans la conf de postgresql `/var/lib/pgsql/data/pg_hba.conf`

## Logs

Les logs se trouvent dans `/var/log/onlyoffice/documentserver/docservice/`

Les logs nginx sont dans `/var/log/onlyoffice/documentserver/nginx.error.log`

# Installation de jupyterHub

## Installation

```
useradd -m -d /srv/jupyterhub jupyter
```

```
chsh jupyter -> /usr/bin/fish
```

```
sudo -i -u jupyter
```

```
npm install -u configurable-http-proxy
```

```
python3 -m pip install --user jupyterhub
```

```
python3 -m pip install --user oauthenticator
```

```
python3 -m pip install --user dockerspawner
```

```
set -U fish_user_paths ~/node_modules/.bin $fish_user_paths
```

```
set -U fish_user_paths ~/.local/bin/ $fish_user_paths
```

```
jupyterhub --generate-config -> a copier en root dans /etc/jupyterhub
```

## Configuration

```
from oauthenticator.generic import GenericOAuthenticator

## Class for authenticating users.

import os

os.environ['OAUTH2_TOKEN_URL'] = 'https://auth.ppsfleet.navy/auth/realms/Ppsfleet/protocol/openid-
connect/token'
os.environ['OAUTH2_AUTHORIZE_URL'] = 'https://auth.ppsfleet.navy/auth/realms/Ppsfleet/protocol/openid-
connect/auth'
os.environ['OAUTH2_USERDATA_URL'] = 'https://auth.ppsfleet.navy/auth/realms/Ppsfleet/protocol/openid-
```

```
connect userinfo'

c.JupyterHub.authenticator_class = GenericOAuthenticator
c.GenericOAuthenticator.login_service = 'Login with PPSfleet'
c.OAuthenticator.client_id = 'jupyterhub'
c.OAuthenticator.client_secret = 'secret'
c.GenericOAuthenticator.oauth_callback_url = 'https://notebook.ppsfleet.navy/hub/oauth_callback'
c.GenericOAuthenticator.userdata_url = 'https://auth.ppsfleet.navy/auth/realms/Ppsfleet/protocol/openid-
connect/userinfo'
c.GenericOAuthenticator.token_url = 'https://auth.ppsfleet.navy/auth/realms/Ppsfleet/protocol/openid-
connect/token'
c.GenericOAuthenticator.userdata_method = 'GET'
c.GenericOAuthenticator.userdata_params = {"state": "state"}
c.GenericOAuthenticator.username_key = "preferred_username"

## The public facing URL of the whole JupyterHub application.

#
# This is the address on which the proxy will bind. Sets protocol, ip, base_url
# Default: 'http://:8000'
c.JupyterHub.bind_url = 'http://127.0.0.1:8002'

## The internal port for the Hub process.

#
# This is the internal port of the hub itself. It should never be accessed
# directly. See JupyterHub.port for the public port to use when accessing
# jupyterhub. It is rare that this port should be set except in cases of port
# conflict.
#
# See also `hub_ip` for the ip and `hub_bind_url` for setting the full bind URL.
# Default: 8081
c.JupyterHub.hub_port = 8081
c.JupyterHub.hub_ip = '0.0.0.0'

c.JupyterHub.spawner_class = 'dockerspawner.DockerSpawner'

## Set the log level by value or name.
# Choices: any of [0, 10, 20, 30, 40, 50, 'DEBUG', 'INFO', 'WARN', 'ERROR', 'CRITICAL']
# Default: 30
c.Application.log_level = 20
```

```
## Set the log level by value or name.  
# See also: Application.log_level  
c.JupyterHub.log_level = 'INFO'
```

# Service

[Unit]

Description=JupyterHub

After=network.target

[Service]

Type=simple

KillMode=mixed

ExecStart=/srv/jupyterhub/.local/bin/jupyterhub -f /etc/jupyterhub/jupyterhub\_config.py

WorkingDirectory=/srv/jupyterhub

Restart=on-failure

[Install]

WantedBy=multi-user.target

# Virtualisation

## Création d'une VM

Pour créer une machine la procédure est la suivante :

- Se déplacer dans le dossier `/root/vms-init`
- Crée l'image de disque à partir de la base de l'os voulu `qemu-img create -f qcow2 -F qcow2 -b /var/lib/libvirt/images/bases/<variante de l'os>.img /var/lib/libvirt/images/storage/<nom de la vm>.img <taille>`
- Modifier le nom de l'instance et l'hostname dans `state/meta-data` :

```
instance-id: <nom de la vm>
local-hostname: <nom de la vm>.vm.ppsfleet.navy
```

- Générer le volume de seed pour cloud-init `genisoimage -output /var/lib/libvirt/images/seeds/<nom de la vm>.iso -volid cidata -joliet -rock state/user-data state/meta-data`
- Démarrer la vm `virt-install --name <nom de la vm> --memory 2048 --vcpu 2 --import --disk path=/var/lib/libvirt/images/storage/<nom de la vm>.img,format=qcow2 --disk path=/var/lib/libvirt/images/seeds/<nom de la vm>.iso,device=cdrom --os-variant <variante de l'os> --network network=vm-net --wait 0`

Script complet:

```
export vm_name=test01
export os_variant=centos-stream8

cd /root/vms-init

qemu-img create -f qcow2 -F qcow2 -b /var/lib/libvirt/images/bases/${os_variant}.img
/var/lib/libvirt/images/storage/${vm_name}.img 20G

cat > state/meta-data <<EOF
instance-id: ${vm_name}
local-hostname: ${vm_name}.vm.ppsfleet.navy
EOF

genisoimage -output /var/lib/libvirt/images/seeds/${vm_name}.iso -volid cidata -joliet -rock state/user-data
```

```
state/meta-data
```

```
virt-install --name ${vm_name} --memory 2048 --vcpu 2 --import --disk  
path=/var/lib/libvirt/images/storage/${vm_name}.img,format=qcow2 --disk  
path=/var/lib/libvirt/images/seeds/${vm_name}.iso,device=cdrom --os-variant ${os_variant} --network  
network=vm-net --wait 0
```

De manière plus automatisée le script `/root/vms-init/create.sh` reprend les commandes ci-dessus pour créer une VM avec 20Go de disque, 2 vCPU et 2Go de mémoire :

```
$ /root/vms-init/create.sh <nom de la vm> <distribution>
```

Distribution disponibles et testées :

Nom	id (variante)
Ubuntu 20.04	ubuntu20.04
Centos 8	centos-stream8
Debian 10	debian10

# Connection

L'utilisateur par défaut est `roger` (mot de passe à voir dans `state/user-data`) et a les droits sudo.

Pour ce connecter en ssh il faut utiliser la clé `/root/.ssh/vm`:

```
ssh roger@${vm_name} -i ~/.ssh/vm
```

Une entrée A et AAAA est rajoutée dans le DNS local pour chaque VM dans la zone `vm.ppsfleet.navy`, qui est défini en tant que domaine de recherche sur alshain et pour les VMs.

L'IPv6 est routé publiquement ainsi on peut se connecter au VMs directement.

# Préparation d'une image

## Activer le client DHCPv6

Certaines distribution utilise seulement une configuration IPv6 stateless (ex. slaac) et il faut activer manuellement le dhcp.

## 1. Monter l'image en lecture/écriture

```
guestmount -a /var/lib/libvirt/images/bases/centos-stream8.img -i -o rw /mnt
```

## 2. Créer le fichier `/mnt/etc/cloud/cloud.cfg.d/10_network.cfg` avec le contenu suivant (**adapter le nom de l'interface par défaut en fonction de l'os**, eth0 pour Centos, enp1s0 pour Debian):

```
network:  
version: 2  
ethernets:  
eth0:  
    dhcp4: true  
    dhcp6: true
```

## 3. Démonter l'image `umount /mnt`

## 4. Sous Debian il faudra aussi modifier la configuration dhcp, dans le fichier

```
/mnt/etc/dhcp/dhclient.conf, remplacer la ligne send host-name = gethostname(); par send  
fqdn.fqdn = gethostname();
```

# OSM

## La recherche

La recherche est sur `search.maps.ppsfleet.navy`, elle utilise Addok

<https://addok.readthedocs.io/en/latest/>

C'est installé dans `/srv/osm/env-addok`, le serveur utilise uwsgi dont la config est dans `/srv/osm/addok`. La config général est dans `/etc/addok`

Les données osm: [https://osm13.openstreetmap.fr/~cquest/osm\\_poi/](https://osm13.openstreetmap.fr/~cquest/osm_poi/)

## Installation fixes

```
pip install setuptools==57.5.0
```

pour fonctionner avec python3.10, besoin de la dernière version de falcon (3.1.0) (cloner les sources et éditer le requirement.txt)

## Le serveur de tuile

## Servir les tuiles

Le serveur de tuile utilise openmaptile, installé dans `/srv/www/maps.ppsfleet.navy/tilesserver.php`, il utilise des fichiers mbtiles, qui sont eux aussi à la racine.

## Le thème

Les thème des cartes se trouvent dans `/srv/www/maps.ppsfleet.navy/tilesserver-data`. Les deux utilisés sont:

- `osm-bright-gl-style/style-cdn.json` (pour `/world`)
- `qwant-basic-gl-style-toulouse/built-style-debug.json` (pour `/toulouse`)

C'est dans ces fichiers .json que le choix du fichier mbtile est défini.

- sources.basemap.tiles
- \_\_\_.poi.tiles

**Pour eviter le cache, on renomme le fichier mbtile à chaque modif avec dd-mm-yy-increment, on doit donc éditer le style par la suite**

**Pour eviter des pbolème de mémoire, dans le docker compose, mettre sous postgres:  
shm\_size: 5gb**

## Générer les tuiles

1. Télécharger un fichier osm.pbf depuis <https://extract.bbbike.org/> pour une zone custom ou depuis <http://download.geofabrik.de/> pour une region ou un pays
2. Editer le schema, openmaptiles.yaml et layers/ ou pas (par default c'est pas si mal)
3. Editer le .env, principalement le `MAX_ZOOM`. Apriori, inutile de le mettre à plus de 14, tout est présent à ce zoom. Et la génération du zoom 16,17,18 prend un temps montrueux ( plusieurs jours pour la france )
4. Supprimer le dossier cache, build, clean le dossier data (ne laisser que le .pbf), supprimer `/var/lib/docker/volumes/openmaptiles_pgdata/`
5. Suivre le tuto de openmaptile <https://github.com/openmaptiles/openmaptiles>:
  - `make destroy-db` # supprime les volumes etc...
  - `make clean` # clean / remove existing build files
  - `make init-dirs` # ??
  - `make all` # ??
  - `make` # generate build files (pareil que make all ??)
  - `make start-db` # start up the database container.
  - `make import-data` # Import external data from OpenStreetMapData, Natural Earth and OpenStreetMap Lake Labels.
  - copy your pbf file to /data
  - `make import-osm` # import data into postgres
  - `make import-wikidata` # import Wikidata
  - `make import-sql` # create / import sql funtions
  - `make generate-bbox-file` # compute data bbox -- not needed for the whole planet
  - `make generate-tiles-pg` # generate tiles (le plus long)

**Toulouse se fait en quelques minutes sur alshain**

**Midi pyrénées se fait en moins d'une heure sur alshain**

**La france se fait en un nombre certains d'heure, si le max\_zoom est pas trop élevé (grand max 16). L'import OSM: 30/35 minutes, Import SQL: 2h30, Génération des tuiles: 17 heures zoom 14**

6. Compiler le thème de quant-maps (je sais plus comment j'avais fait)

<https://github.com/Qwant/quant-basic-gl-style>

## Le front-end

Il est dans `/srv/www/maps.ppsfleet.navy/front/{world|toulouse}`, c'est basé sur <https://github.com/tjiho/simplestreetmap>, avec l'utilisation de maplibre.

TODO: responsive sur telephone

## Les itinéraires

Todo.

On pourrait se baser sur brouter. Voir aussi <https://safecycle.atelier-des-communs.fr/>

ou <https://navitia.io/>

## Ajouter des données

J'ai mis en place pg\_tileserv. Il détecte automatiquement les tables postgis, et les transforme en tuile.

Il a son home dans `/srv/pg-tileserv` et sa conf dans `/etc/pg-tileserv`

## Générer des tuiles "raster" en node-js

```
git clone https://github.com/maplibre/maplibre-gl-native
```

```
dnf groupinstall "Development Tools" "Development Libraries"
```

```
dnf install glfw-devel freeglut-devel libuv-devel libXrandr-devel libjpeg-devel zlib-devel libpng-devel g++ mesa-dri-drivers xorg-x11-server-Xvfb
```

A la racine du repo:

```
cmake . -B build
```

```
vim vendor/benchmark/src/benchmark_register.h  
> #include <vector>  
> #include <limits>
```

```
vim build/CMakeCache.txt  
> CMAKE_CXX_FLAGS:STRING=-pthread
```

```
cmake --build build
```

ca va planter en essayant de compiler la partie nodejs (aux alentours de 90%), c'est pas grave tant que ca plante pas avant

## Générer l'image

```
run.sh  
> /srv/osm/maplibre-gl-native/build/bin(mbgl-render --style=https://maps.ppsfleet.navy/tileserv...  
basic-gl-style-toulouse/built-style-debug.json --output=test.png --width=512 --height=256 --lon=1.4436 --  
lat=43.6042 --zoom=13
```

```
xvfb-run ./run.sh
```

## Idée theme

# Simplestreetmap

# Les "plugins"

Un plugin serait un fichier js qui ajouterait des fonctionnalité optionnelles à simplestreetmap

Le premier serait velotoulouse.

## Design (code)

- un icone et un nom à afficher dans le menu
- un objet js qui interagit avec la carte
- un composant html (dans un aside)
- un composant html (pour du fullscreen)
- un état (actif/inactif)

# Architecture

## Le websocket

- client -> hello {token}
- server <- "hello", {data}

## actions

- add, {annotation}
- remove, {annotationId}
- hide, {annotationId}
- show, {annotationId}

# Todo

## Avant mise en ligne

### Les annotations

- : cacher / afficher
- : éditer
  - : couleur
  - : nom
  - : horaire... (depend du calendrier, pour plus tard)
- : supprimer
- : afficher une icone selon le type d'annotation
- : au clic -> centrer la carte dessus et affichage du detail dans l'onglet correspondant
  - place
  - itinéraires
    - centrer la carte
    - afficher le detail
- ajout de sources externes (cameras)

### Les itinéraires

#### Pour le multi modal

- afficher les horaires et les correspondances

#### Pour le vélo

- afficher le dénivelé (optionnel mais ca serait cool)

# Général

- style des formulaire
- afficher si pas d'itinéraire
- loader qui tourne
- fichier de license dans le folder breeze
- mettre à jour le README
- partage/sauvegarde de la carte (avec un token ou dans le localStorage ?)
  - reflexion sur l'édition collaborative (quid des conflits, si partage du token)
- inverser les champs from et to avec un bouton
- clic droit -> menu -> "itinerary from/to" "add a point" "force itinerary to pass at this point"

# Edition collaborative

- Ajout place
- suppr place
  - remove\_annotation côté serveur
  - listener côté client
- edition place
- ajout itinéraire
- suppr itinéraire

# Truc à ajouter aussi

- des infos sous la recherche
- demarrer un itinéraire d'une annotation
- clic sur un poi pour avoir des infos
- affichage temporel des annotations

- affichage du cadastre ou de l'ign ou des photo aerienne de l'ign
- sauvegarde des infos en bdd pour pouvoir partager la carte
- ajout d'annotation dessiné (rectangle, path mais fait à la main)
- simple calcul de distance à vol d'oiseau
- recherche basé sur la localisation courante
- afficher les horaires d'un bus en cliquant sur l'arrêt
- rendre responsive
- thème nuit
- traduction en français et autres langues

## Truc vraiment stylé un jour

- édition collaborative !
- redirection pour acheter son billet
- gps de voiture, et affichage des bouchons (même si vive le vélo et le train)
- synchro avec un calendrier
- syncro avec un compte apple ou google (pour aider à la migration)

## Truc de devops

- rebuild les tuiles une fois par mois
- rebuild de l'index de la recherche régulièrement

# Cameras

## Importer les données avec OSM2PGSQL

```
docker run --name postgis -e POSTGRES_PASSWORD=password -p 5432:5432 -d postgis/postgis
```

```
local cameras = osm2pgsql.define_node_table('cameras', {  
  { column = 'id', sql_type = 'serial', create_only = true },  
  { column = 'geom', type = 'point' },  
})
```

```
local highways = osm2pgsql.define_way_table('highways', {  
  { column = 'id', sql_type = 'serial', create_only = true },  
  { column = 'geom', type = 'linestring' },  
})
```

```
local buildings = osm2pgsql.define_area_table('buildings', {  
  { column = 'id', sql_type = 'serial', create_only = true },  
  { column = 'geom', type = 'polygon' },  
})
```

```
function osm2pgsql.process_node(object)  
  if object.tags.man_made == 'surveillance' then  
    cameras:insert({  
      geom = object:as_point()  
    })  
  end  
end
```

```
function osm2pgsql.process_way(object)

# Profils brouter

C'est pas ouf, mais pour le POC, j'ai réussi à modifier le fichier trekking en mettant:

```

assign camera = camera=yes

assign turncost = if camera then 86000 else if is_ldcr then 0
else if junction=roundabout then 0
else 90

```

# Pour tester

brouter-web (c'est du statique)

<https://github.com/nrenner/brouter-web>

# Tiles from postgis

```
export DATABASE_URL=postgresql://postgres:password@localhost/postgres  
~/bin/pg_tileserv_latest_linux/pg_tileserv
```

# fix psql import

```
create or replace function cast_to_city_place(text) returns city_place as $$  
begin  
    return cast($1 as city_place);  
exception  
    when invalid_text_representation then  
        return 'town';  
end;  
$$ language plpgsql immutable;  
  
ALTER TABLE osm_city_point  
    ALTER COLUMN place TYPE city_place USING cast_to_city_place(place);
```

# Addok

## Création des données

### Package (fedora)

- postgis-client
- osmctools

## Commands

```
podman run --name postgis -e POSTGRES_PASSWORD=mysecretpassword -p 127.0.0.1:54321:5432 -d postgis/postgis

export PGPASSWORD=mysecretpassword
psql -h 127.0.0.1 -p 54321 -Upostgres -c "CREATE EXTENSION unaccent"
```

puis

- Cloner <https://github.com/osm-fr/osmpoi4addok>
- Remplacer tout les appels à psql par `psql -h 127.0.0.1 -p 54321 -Upostgres`
- Editer `30-extract-poi.sh` et mettre `PBF_NAME` avec le bon nom
- Compiler `osmfilter` et `osmconvert` depuis les sources: <http://m.m.i24.cc/osmfilter.c> et <http://m.m.i24.cc/osmconvert.c>
- Lancer les script un par un

Sur ma tour (rizen 5), en dehors des téléchargements, midi pyrénées se fait en quelques minutes

# Update tiles

## Télécharger le diff

```
source env-openmaptiles/bin/activate.fish  
pyosmium-get-changes -O france.osm.pbf -o changes.osc.gz
```

Pour 1 mois et demi de diff: instantané

## Importer le diff

```
make import-diff
```

Pour 1 mois et demi de diff: une 10aine de minutes

## Générer les tuiles

```
make generate-changed-tiles
```

# Mumble

room.fede.re

## Server

Le serveur est `murmur`, avec sa config dans `/etc/murmur/murmur.ini`

`ps -aux | grep murmurd` ou `ps -aux | grep mumble-server` pour savoir si il est démarré (todo: faire un service)

Pour le demmarer: `murmurd`

## Proxy websocket

<https://github.com/Johni0702/mumble-web-proxy>

Le proxy websocket est dans `/srv/mumble-web-proxy`

## Install

Il y a une erreur dans la build, voir issue: <https://github.com/Johni0702/mumble-web-proxy/issues/31>

Il faut installer <https://rustup.rs/>

Puis `~/.cargo/bin/rustup default 1.48.0`

Et `~/.cargo/bin/cargo build release`

## Run

`target/release/mumble-web-proxy --listen-ws 64737 --server room.fede.re:64738`

## Usage

L'utilisateur admin est `SuperUser`.

# ttrss

## Config

```
putenv('TTRSS_DB_HOST=localhost');
putenv('TTRSS_DB_USER=feeds');
putenv('TTRSS_DB_NAME=feeds');
putenv('TTRSS_DB_PASS=...');
putenv('TTRSS_DB_PORT=3306');
putenv('TTRSS_DB_TYPE=mysql');
putenv('TTRSS_SELF_URL_PATH=https://feeds.ppsfleet.navy');
putenv('TTRSS_PHP_EXECUTABLE=/usr/bin/php'); # normally something like /usr/bin/php
```

Le plugin `af_readability` est bien utile pour télécharger le contenu des articles (à activer dans les paramètre puis pour chaque feed)

L'option `Mark read on scroll` est aussi sympa.

## Thème custom

le thème de base est pas ouf, surtout pour la lecture des articles (un peu la fonctionnalité principale d'un lecteur rss)

OMG! Ubuntu!

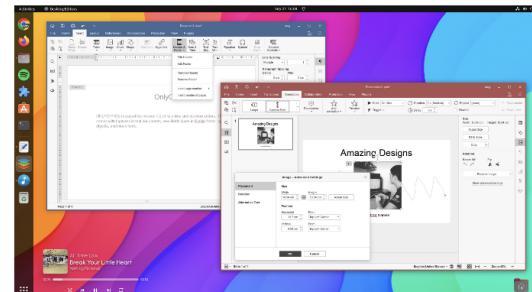

ONLYOFFICE 7.2 Released with Misc New Features & Improvements Joey Sneddon Sep 27, 17:18 →

An updated version of ONLYOFFICE is available to download for Windows, macOS, and Linux.

ONLYOFFICE 7.2 ships with all of the latest changes to the online version, plus some 'unique features' exclusive to the desktop editors, including automatic light/dark mode on Windows and macOS (the feature is present on Linux builds but doesn't, in my testing, do what it should).

Such as? Well, the new version of the Document has ligature support in text files; lets you easily insert the current heading into a table of contents; and adds a new "Headings" panel to the main toolbar (replacing the navigation panel). Converting .pdf, .djvu, and .xps documents to .docx is also said to have improved.

The Presentation tool now supports custom path animations, offers advanced settings, is able to playback audio and video in slides without requiring VLC, and intros advanced "placement" options for images, when selecting an image and choosing 'advanced settings'.

New features in Document and Presentation

.cdm.expandable.active, .cdm.expanded

```
{
    max-width:1000px;
    margin-left:auto;
    margin-right:auto;
    background-color: white;
    /*box-shadow: 1px 1px 18px rgba(0,0,0,0.1);*/
    margin-top:15px;
    padding:20px;
    border-bottom: 2px solid;
    width: 90%;
}
```

```
}
.cdm .content-inner {
    font-family: 'Liberation Serif' !important;
    font-size: 18px !important;
    line-height: 1.5em !important;
    font-weight: 300 !important;
    color: #333 !important;
}
```

```
.cdm .content {
    max-width:800px;
```

```
margin:auto;  
}  
  
.cdm.dijitBorderContainerPane {  
    position:initial !important;  
}  
  
#headlines-wrap-inner,#headlines-frame  
{  
/*background-color: #e6e6e6;*/  
}  
  
.cdm.expanded .footer {  
    border:none !important;  
}  
  
.cdm.expandable.active .header[data-is-stuck], .cdm.expanded .header[data-is-stuck] {  
    margin-top: 10px !important;  
    box-shadow: rgba(0, 0, 0, 0.3) 2px 2px 18px !important;  
    border-color: grey !important;  
    border-width: 1px 1px !important;  
    border-style: solid !important;  
    top:1px;  
}
```

# NTFY

NTFY est un serveur push pour gerer entre autre les notif sur android sans passer par les serveurs google.

C'est un peu du mqtt, mais c'est pas du mqtt.

## Coté serveur (sur alshain)

j'ai suivi la doc (en gros): <https://docs.ntfy.sh/install/>

```
sudo rpm -ivh https://github.com/binwiederhier/ntfy/releases/download/v1.30.1/ntfy_1.30.1_linux_amd64.rpm4
```

la config: /etc/ntfy/server.yml

le service: ntfy

le domaine: ntfy.fede.re

le socket: /var/lib/ntfy/ntfy.sock

## Coté client (sur le tel)

Installer ntfy via fdroid.

Puis configurer les notifs de vos app de libriste pour passer par ntfy. (La plupart des client matrix et des clients mastodon)

Oh, et désactiver l'optimisation de batterie pour ntfy.

# openvpn

## Start

```
systemctl start openvpn-server@server.service
```

## La conf

```
client
tls-client
ca /path/to/ca.crt
cert /path/to/client.crt
key /path/to/client.key
tls-crypt /path/to/alshain.tlsauth
;remote-cert-eku "TLS Web Client Authentication"
remote-cert-eku 1.3.6.1.5.5.7.3.1
proto udp
cipher AES-256-CBC
remote alshain.ppsfleet.navy 1194 udp
dev tun
topology subnet
pull
;user nobody
;group nobody
```

## Générer un certificat

```
# todo
```

# REDIS

on doit éditer le fichier /etc/systemd/system/redis.service.d/limit.conf avec

```
[Service]
LimitNOFILE=10240
TimeoutStartSec=300s
TimeoutStopSec=300s
```

# jitsi

## Installation

```
dnf install maven prosody
```

```
prosodyctl cert generate meet.fede.re
prosodyctl cert generate auth.meet.fede.re
ln -s /var/lib/prosody/auth.meet.fede.re.crt /etc/pki/ca-trust/source/anchors/
update-ca-trust
prosodyctl register focus auth.meet.fede.re <secret_str>
systemctl start prosody
```

```
useradd jitsi -m -s /usr/bin/fish -d /srv/jitsi
sudo -iu jitsi
wget https://github.com/jitsi/jitsi-videobridge/archive/refs/tags/stable/jitsi-meet_9364.zip
unzip jitsi-meet_9364.zip
mv jitsi-videobridge-stable-jitsi-meet_9364/ jitsi-2.0.9364
cd jitsi-2.0.9364
```

Edit pom.xml

```
<properties>
...
<user.language>en</user.language>
<argLine>-Duser.language=${user.language}</argLine>
</properties>
```

```
mvn install
```

# Etherpad

```
root ~ # useradd -m -r -d /opt/etherpad -U etherpad
root ~ # sudo -iu etherpad git clone https://github.com/ether/etherpad-lite
root ~ # sudo -iu etherpad npm config set prefix '~/.local/'
root ~ # sudo -iu etherpad npm install -g pnpm

etherpad ~ % fish_add_path ~/.local/bin/
etherpad ~/etherpad-lite % ~/.local/bin/pnpm run plugins install ep_delete_after_delay
```

Image de fond modifiée : `src/static/skins/colibris/images/fond.jpg`

Modification du `settings.json` :

```
{
  "title": "Pad.fede.re",
  "favicon": "favicon.ico",

  "ip": "127.0.0.1",
  "port": 8679,

  "cleanup": {
    "enabled": true,
    "keepRevisions": 100
  },

  "ep_delete_after_delay": {
    "delay": 15552000, // 60 seconds * 60 minutes * 24 hours * 30 days * 6 = 6 months, in seconds
    "loop": true,
    "loopDelay": 3600, // one hour, in seconds
    "deleteAtStart": true,
    "text": "The content of this pad has been deleted since it was older than the configured delay."
  },

  "users": {
    "admin": {
      "password": "changeme",
```

```
    "is_admin": true
  }
},
}
```

Fichier du service systemd:

```
cat /etc/systemd/system/etherpad.service
[Unit]
Description=etherpad
After=network.target

[Service]
Type=simple
KillMode=mixed
User=etherpad
Environment=PATH=/opt/etherpad/.local/bin:/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin:/var/lib/snap
d/snap/bin
Environment=NODE_ENV=production
ExecStart=/bin/sh /opt/etherpad/etherpad-lite/bin/run.sh
WorkingDirectory=/opt/etherpad/etherpad-lite
Restart=on-failure

[Install]
WantedBy=multi-user.target
```
